

# Your first hybrid application

fork and edit tutorial (<https://github.ibm.com/MFPSamples/DevCenter/tree/master/tutorials/en/foundation/7.1/hello-world/your-first-hybrid-application.html>) | report issue (<https://github.ibm.com/MFPSamples/DevCenter/issues/new>)

## Overview

This tutorial describes all the steps from creating a new MobileFirst project and Hybrid application to building it. The tutorial explains the structure of the new Hybrid application and all its components, as well as the concept of "Single-Page Application" (SPA) that MobileFirst Hybrid applications are based on.

## Agenda:

- Creating a hybrid application
- Adding environments
- Structure of a new application
- Single DOM model
- Building the application
- Previewing the application
- Tutorials to follow next

## Creating a hybrid MobileFirst application

### Using the command-line interface (CLI)

1. If you have installed the CLI (`../../advanced-client-side-development/using-cli-to-create-build-and-manage-mobilefirst-project-artifacts/`), in the terminal, create a project named `HelloWorldProject`.

```
$ mfp create HelloWorldProject
A MobileFirst Project was successfully created at /Users/MyUser/Dev/HelloWorldProject
```

2. Go to the context of your newly created project.

```
$ cd HelloWorldProject/
```

3. Define a hybrid application named `HelloWorld`.

```
$ mfp add hybrid HelloWorld
A new Hybrid App was added at /Users/MyUser/Dev/HelloWorldProject/apps/HelloWorld
```

### Using the Studio

1. In MobileFirst Studio, select **File > New > MobileFirst Project** to create a new MobileFirst Project from the top toolbar.

2. Give your project a name, for example *HelloWorldProject*, and select the **Hybrid Application** template.

3. Give the application a name, for example *HelloWorld*. You can add JavaScript frameworks to your project in this screen. Click **Finish** when done.

To learn more about adding frameworks to applications, read the [Client-side development basics > Working with UI frameworks \(../../client-side-development-basics/working-with-ui-frameworks/\)](#) tutorial.

## Adding Environments

A MobileFirst environment is a platform on which a Hybrid application can run on. These environments are separated into three groups: Mobile environments, Web environments and Desktop environments.

- Mobile environments: iOS, Android, Windows Phone 8, Windows 8 and BlackBerry 10.
- Web environments: Mobile Web, Desktop Browser
- Desktop environments: Air

To add an environment:

## Using the command-line interface (CLI)

Navigate to the Hybrid application and add an environment:

```
cd apps/HelloWorld  
mfp add environment
```

## Using the Studio

1. Click the MobileFirst icon in the menu bar and select **MobileFirst Environment**.

2. Select the application to which you would like to add an environment and select one or more environments.
3. Click **Finish**. A new folder with the environment name is added to the project structure.

## Structure of the new application

## Environment files

### Common

The default environment is called **common**. The **common** environment contains all the resources that are shared between environments:

- **index.html**: the main HTML file
- **css**
  - `main.css`: the main application CSS file
- **images**: default MobileFirst images for the common environment
- **js**
  - `initOptions.js`: Used for defining the initialization options of the application. See the documentation of the `WL.Client.init` method in the API reference part of the user documentation
  - `main.js`: the main JavaScript file for the application
  - `messages.js`: Contains A JSON object that holds all app messages. Can be used as the source for translation
- **legal**: A folder that holds all the legal docs
- **application-descriptor.xml**: Contains the application metadata
- **build-settings.xml**: Contains configuration options for minification and concatenation

### Environments

The screen shot to the right depicts the iPhone environment, but the explanation below applies to any mobile environment (iPhone, iPad, Android, BlackBerry, Windows Phone 8, Windows 8).

The mobile environment includes the following folders:

- **CSS** – The properties that are specified in this folder override the CSS files from the common folder.
- **Images** – You can add environment-specific images in this folder. If images with the same file names exist in the common folder, they are overwritten in the application.
- **JavaScript** – Contains JavaScript that can extend, and override if necessary, JavaScript from the common folder.
- The **native** folder contains automatically generated native project code. Files in the `native\www` folder are regenerated each time the application is built. Any changes that are made to these files are lost.
- The **nativeResources** folder contains resources that are used by the native code.

#### Note about Android

After you add the Android environment, an Android project is generated and added to the workspace.

This project folder does not contain a copy of the application code. Rather, it is mapped to the native folder within the android folder of the application.

## Server files

- **externalServerLibraries**: Contains the libraries to be placed in external service servers and used for access token validation (by the service).
- **server**: Contains files that are used for server-side customization of a project:
  - **conf**: contains
    - **authenticationConfig.xml**: Defines authentication realm and security tests
    - **default.keystore**: A default SSL certificate that is provided by the project
    - **login.html**: Presents a login form for web environments and the MobileFirst Operations Console
  - **SMSConfig.xml**: Defines SMS Gateways
  - **worklight.properties**: Defines the properties that are used by MobileFirst Server
- **java**: Used to hold Java classes that will be compiled and deployed to a MobileFirst Server instance after the application is built. You can place your custom Java code here.
- **lib**: Used for JAR files that are deployed to the server
- **services**: Contains any back-end services that were discovered

## The bin folder

The `bin` folder contains project artifacts that are deployed to MobileFirst Server. MobileFirst Studio deploys those artifacts to the embedded MobileFirst Development Server automatically as a part of the build process.

- `.wlapp` files are application bundles.
- `.wladapter` files are adapters.
- `.jar` and `.war` files are server customization files that contain `worklight.properties`, `authenticationConfig.xml`, and custom Java code.

## The application-descriptor.xml file

The application descriptor is an XML file that stores the metadata for an application. You can edit this file in the Design or Source editors.

The file is based on the W3C Widget Packaging and Configuration standard and contains application properties that are used at build time.

You can specify the application description, details about the author, the thumbnail image to be displayed in the MobileFirst Operations Console, and more.

```

<!-- Attribute "id" must be identical to application folder name -->
<application id="HelloWorld" platformVersion="7.1.0.00.20150701-1029"
xmlns="http://www.worklight.com/application-descriptor"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"></p>
<p>    <displayName>HelloWorld</displayName>
    <description>HelloWorld</description>
    <author>
        <name>application's author</name>
        <email>application author's e-mail</email>
        <copyright>Copyright My Company</copyright>
        <homepage>http://mycompany.com</homepage>
    </author>
    <mainFile>index.html</mainFile>
    <thumbnailImage>common/images/thumbnail.png</thumbnailImage>
>
    <features>
    </features>
    <targetCategory>UNDEFINED</targetCategory>
</application>

```

Environment-specific information is inserted automatically as new environments are added to the MobileFirst project:

```

<iphone bundleId="com.HelloWorld" version="1.0">
    <worklightSettings include="false"/>
    <security>
        <encryptWebResources enabled="false"/>
        <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4,
mp3"/>
    </security>
</iphone>
<android version="1.0">
    <worklightSettings include="false"/>
    <security>
        <encryptWebResources enabled="false"/>
        <testWebResourcesChecksum enabled="false" ignoreFileExtensions="png, jpg, jpeg, gif, mp4,
mp3"/>
        <publicSigningKey/>
        <packageName/>
    </security>
</android>

```

Learn more about the `application-descriptor.xml` file in the user documentation.

## The build-settings.xml file

The build settings file is an XML file that contains configuration options for minification and concatenation of the Desktop Browser and Mobile Web environment web resources.

You can edit this file in the Design or Source editors.

By using minification on specific web resources, you can reduce the size of JavaScript and CSS files in the application.

In addition, you can use concatenation of the web resources to improve the start time of the application.

## The index.html file

At application run time, the main HTML document cannot be replaced by another HTML document.

The default application HTML template complies with HTML5 standard markup, but any other DOCTYPE can be specified.

The MobileFirst client-side framework uses the jQuery library for internal functions. By default, the `$` char is assigned to the internal jQuery in the main HTML file (see below). If a different jQuery version is required or if jQuery is not required in the application, this line (#12) can be removed.

The MobileFirst client framework initialization is bound to the `onload` event specified in the `initOptions.js` file. For more information about initialization options, see the user documentation.

```

<!DOCTYPE HTML>
<html>
  <head>
    <meta charset="UTF-8">
    <title>HelloWorld</title>
    <meta name="viewport" content="width=device-width, initial-scale=1.0, maximum-scale=1.0,
minimum-scale=1.0, user-scalable=0">
    <!--
      <link rel="shortcut icon" href="images/favicon.png">
      <link rel="apple-touch-icon" href="images/apple-touch-icon.png">
    -->
    <link rel="stylesheet" href="css/main.css">
    <script>window.$ = window.jQuery = WLJQ;</script>
  </head>
  <body style="display: none;">
    <!--application UI goes here-->
    Hello World
    <script src="js/initOptions.js"></script>
    <script src="js/main.js"></script>
    <script src="js/messages.js"></script>
  </body>
</html>

```

## The initOptions.js file

The initialization options file contains MobileFirst framework initialization settings. It is also responsible for initializing the MobileFirst framework after the `body` element finishes loading.

By default, the MobileFirst application starts in offline mode (the application does not attempt to connect to MobileFirst Server).

To connect to MobileFirst Server, use `WL.Client.connect()`.

Some default initialization options are documented in the file itself. The entire set of options is documented in the Reference topic for the API method `WL.Client.init`, in the user documentation.

## The main.js file

When you create an application, a `main.js` file is created and holds its JavaScript portion. It contains a `wlCommonInit()` function which is invoked automatically after the MobileFirst framework initialization finishes. Application initialization code can be implemented herein.

This function is used in environment-specific JavaScript files to have a common initialization starting point. Additional details are provided in subsequent tutorials.

As discussed previously, the MobileFirst application starts in offline mode by default. To begin communicating with MobileFirst Server, follow the instructions provided in the default `wlCommonInit()` function:

```
function wlCommonInit(){
    /*
     * Use of WL.Client.connect() API before any connectivity to MobileFirst Server is required.
     * Call this API only once, before any other WL.Client methods that communicate with MobileFirst Serv
    er.
     * Remember to specify and implement the onSuccess and onFailure callback functions for WL.Client.
    connect(), e.g:
     *
     * WL.Client.connect({
     *     onSuccess: onConnectSuccess,
     *     onFailure: onConnectFailure
     * });
     *
     */
    // Common initialization code goes here</p>
}<
```

## Building an application

### Using the command-line interface (CLI)

Navigate to the application folder and use the `push` command to build and deploy the application to the MobileFirst Server.

```
mfp push
```

### Using MobileFirst Studio

To build an application, right-click the application name and select **Run As > Run on MobileFirst Development Server**.

While the application is being built and deployed, you can monitor the progress in the Eclipse Console view. After the build completes, the application is available for preview in the catalog tab of the MobileFirst Operations Console.

Most JavaScript UI frameworks available today (for example, jQuery Mobile, Dojo Mobile, Sencha Touch) provide an extensive range of APIs to achieve the required multipage navigation.

This module explains the principles of a single-page application.

Principles of multipage applications that are built with a single DOM model are explained in other tutorials.

## Previewing an Application

### Using the command-line interface (CLI)

From the application preview, use the `preview` command, and select preview mode: Simple preview or MBS.

```
mfp preview
```

### Using MobileFirst Studio

To preview the application's common resources from the Studio, right-click the `common` folder and choose **Run As > Preview**.

If you are presented with a login screen, use admin/admin as the username/password.

To learn more about previewing, see the [Previewing your Hybrid Application \(../../hello-world/previewing-your-hybrid-application/\)](#) tutorial.

## Tutorials to follow next

Now that you created your first hybrid application, you can follow the tutorials in the [Hybrid client-side development \(../client-side-development-basics/\)](#) section to learn more about authentication and security, server-side development, advanced client-side development, notifications, and more.
