# Implementing the challenge handler in iOS applications

#### Overview

**Prerequisite:** Make sure to read the **CredentialsValidationSecurityCheck** challenge handler implementation (../../credentialsvalidation/ios/) tutorial.

The challenge handler tutorial demonstrates a few additional features (APIs) such as preemptive login, logout, and obtainAccessTokenForScope.

## Login

In this example, <u>UserLogin</u> expects *key:value*s called <u>username</u> and <u>password</u>. Optionally, it also accepts a Boolean <u>rememberMe</u> key, which tells the security check to remember this user for a longer period. In the sample application, this is collected by a Boolean value from a checkbox in the login form.

The credentials argument is a JSONObject containing username, password, and rememberMe:

```
self.submitChallengeAnswer(credentials);
```

You might also want to log in a user without any challenge being received. For example, you can show a login screen as the first screen of the application, or show a login screen after a logout or a login failure. Those scenarios are called **preemptive logins**.

You cannot call the submitChallengeAnswer API if no challenge to answer. For those scenarios, the MobileFirst Foundation SDK includes the login API:

```
WLAuthorizationManager.sharedInstance().login(self.securityCheckName, withCredentials: credentials) { (error) -> Void in
if(error != nil){
    NSLog("Login Preemptive Failure: " + String(error))
}
else {
    NSLog("Login Preemptive Success")
}
```

If the credentials are wrong, the security check sends back a **challenge**.

It is the developer's responsibility to know when to use <code>login</code>, as opposed to <code>submitChallengeAnswer</code>, based on the application's needs. One way to achieve this is to define a Boolean flag, for example <code>isChallenged</code>, and set it to <code>true</code> when <code>handleChallenge</code> is reached, or set it to <code>false</code> in any other cases (failure, success, initialization, etc).

When the user clicks the Login button, you can dynamically choose which API to use:

```
if(!self.isChallenged){
   WLAuthorizationManager.sharedInstance().login(self.securityCheckName, withCredentials: credentials) { (error) -> Void in}
}
else{
   self.submitChallengeAnswer(credentials)
}
```

**Note:** The WLAuthorizationManager login() API has its own completion handler, the relevant handleSuccess or handleFailure methods of the relevant challenge handler ore **also** called.

## Obtaining an access token

Because this security check supports the **RememberMe** functionality (as the rememberMe Boolean key), it would be useful to check whether the client is currently logged in when the application starts.

The MobileFirst Foundation SDK provides the obtainAccessTokenForScope API to ask the server for a valid token:

```
WLAuthorizationManager.sharedInstance().obtainAccessTokenForScope(scope) { (token, error) -> Void in
   if(error != nil){
      NSLog("obtainAccessTokenForScope failed: " + String(error))
   }
   else{
      NSLog("obtainAccessTokenForScope success")
   }
}
```

**Note:** The WLAuthorizationManager obtainAccessTokenForScope() API has its own completion handler, the handleSuccess or handleFailure of the relevant challenge handler are **also** called.

If the client is already logged-in or is in the *remembered* state, the API triggers a success. If the client is not logged in, the security check sends back a challenge.

The obtainAccessTokenForScope API takes in a scope. The scope can be the name of your security check.

Learn more about **scopes** in the Authorization concepts (../../) tutorial.

### Retrieving the authenticated user

The challenge handler handleSuccess method receives a dictionary success as a parameter. If the security check sets an AuthenticatedUser, this object contains the user's properties. You can use handleSuccess to save the current user:

```
override func handleSuccess(success: [NSObject : AnyObject]!) {
    self.isChallenged = false
    self.defaults.setObject(success["user"]!["displayName"]! as! String, forKey: "displayName")
}
```

Here, success has a key called user which itself contains a dictionary representing the AuthenticatedUser:

```
{
    "user": {
        "id": "john",
        "displayName": "john",
        "authenticatedAt": 1455803338008,
        "authenticatedBy": "UserLogin"
    }
}
```

### Logout

The MobileFirst Foundation SDK also provides a Logout API to logout from a specific security check:

```
WLAuthorizationManager.sharedInstance().logout(self.securityCheckName){ (error) -> Void in
if(error != nil){
   NSLog("Logout Failure: " + String(error))
}
```

## Sample applications

Two samples are associated with this tutorial:

- PreemptiveLoginSwift: An application that always starts with a login screen, using the preemptive login API.
- RememberMeSwift: An application with a Remember Me checkbox. The user can bypass the login screen the next time the
  application is opened.

Both samples use the same UserLogin security check from the SecurityCheckAdapters adapter Maven project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/SecurityCheckAdapters/tree/release80) the SecurityCheckAdapters Maven project.

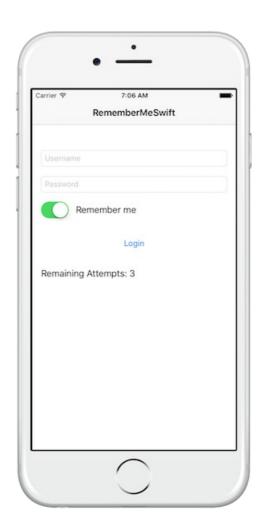

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/RememberMeSwift/tree/release80) the Remember Me project.

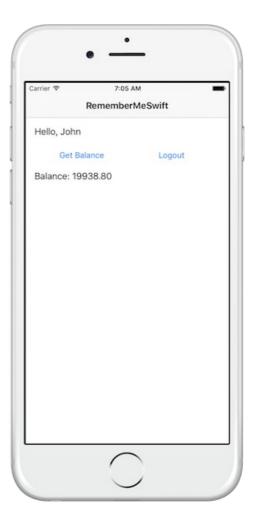

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/PreemptiveLoginSwift/tree/release80) the Preemptive Login project.

#### Sample usage

Follow the sample's README.md file for instructions.

The username/password for the app must match, i.e. "john"/"john".
