Tag and Broadcast Notifications in Native Windows 8 Applications

- Download MobileFirst project (https://github.com/MobileFirst-Platform-Developer-Center/TagNotifications)
- Download Native project (https://github.com/MobileFirst-Platform-Developer-Center/TagNotificationsWin8)

Overview

Prerequisite: Make sure that you read the Push notifications in native Windows 8 applications (../) tutorial first.

Tag notifications are notification messages that are targeted to all the devices that are subscribed to a particular tag.

Tags represent topics of interest to the user and provide the ability to receive notifications according to the chosen interest.

Broadcast notifications are a form of tag push notifications that are targeted to all subscribed devices. Broadcast notifications are enabled by default for any push-enabled MobileFirst application by a subscription to a reserved Push.all tag (auto-created for every device). This ability can be disabled by by unsubscribing from the reserved Push.all tag.

Agenda

- Notifications configuration
- Notifications API
- Sample application

Notifications configuration

Tag Notifications configuration

Setting up tags

</tag>

Tags are defined in the application-descriptor.xml file:

[code lang="xml"]<nativeWindows8App xmlns="http://www.worklight.com/native-windows8-descriptor" id="NativeWin8TagNotifications" platformVersion="7.0.0.00.20150312-0731" version="1.0">

```
<pushSender clientSecret="WNS_CLIENT_SECRET" packageSID="WNS_PACKAGE_SID"/>
...
...
<tags>
<tags>
<name>my tag 1</name>
<description>About my tag 1</description>
```

<name>my tag 2</name>
<description>About my tag 2</description>
</tag>
</tag>>[/code]

Notifications API

API methods for tag notifications

Client-side API

- WLPush.subscribeTag(tagName,options) Subscribes the device to the specified tag name.
- WLPush.unsubscribeTag(tagName,options) Unsubscribes the device from the specified tag name.
- WLPush.isTagSubscribed(tagName) Returns whether the device is subscribed to a specified tag name.

Common API methods for tag and broadcast notifications

Client-side API

- WLNotificationListener
 - Defines the callback method to be notified when the notification arrives.
- WLPush.notificationListener = new MyNotificationListener();
 Sets the implementation class of the WLNotificationListener interface.
- WLPush.onReadyToSubscribeListener
 - This method registers a listener to be used for push notifications. This listener should implement the onReadyToSubscribe() method.
- The onMessage(props,payload) method of WLNotificationListener is called when a push notification is received by the device.
 - props A JSON block that contains the notifications properties of the platform.
 - payload A JSON block that contains other data that is sent from MobileFirst Server. The
 JSON block also contains the tag name for tag-based or broadcast notification. The tag name
 appears in the "tag" element. For broadcast notification, the default tag name is Push.ALL.

Server-side API

WL.Server.sendMessage(applicationId, notificationOptions)

This method submits a notification based on the specified target parameters and takes two mandatory parameters:

- applicationId (mandatory) The name of the MobileFirst application
- notificationOptions (mandatory) A JSON block containing message properties

For a full list of message properties, see the WL.Server.sendMessage API in the API reference of the user documentation.

Sample application

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/TagNotifications) the MobileFirst project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/TagNotificationsWin8) the Native project.

- The TagNotifications project contains a MobileFirst native API that you can deploy to your MobileFirst Server instance.
- The TagNotificationsWin8 project contains a native Windows 8 Universal application that uses a
 MobileFirst native API library to subscribe to push notifications and receive notifications from
 Windows Notification Services (WNS).
- Make sure to update the wlclient.properties file in the native project with the relevant server settings.

Sending a notification

To test the application is able to receive a push notification you can perform one of the following:

- 1. From MobileFirst Studio, right-click the adapter folder, select **Call MobileFirst Adapter** and:
 - If selecting the "sendBroadcastNotification" procedure, provide the application ID and notification text in quotation marks.
 - If selecting the "sendTagNotification" procedure, provide the application ID, notification text and tag name in quotation marks.
 - The application ID can be determined from the id attribute in application-descriptor.xml: [code lang="xml"]<application ... id="NativeWin8TagNotifications" ...>[/code]
- 2. If using the CLI:

[code lang="shell" title="Broadcast language=notification"]\$ mfp adapter call

- [?] Which endpoint do you want to use? PushAdapter/sendBroadcastNotification
- [?] Enter the comma-separated parameters: "NativeWin8TagNotifications", "hello"
- [?] How should the procedure be called? GET[/code]

Or:

[code lang="shell" title="Tag language=notification"]\$ mfp adapter call

- [?] Which endpoint do you want to use? PushAdapter/sendTagNotification
- [?] Enter the comma-separated parameters: "NativeWin8TagNotifications", "hello", "sample-tag1"
- [?] How should the procedure be called? GET [/code]
