Tag and Broadcast Notifications in Native Android Applications

Overview

Prerequisite: Make sure that you read the Push notifications in native Android applications (../) tutorial first.

Tag notifications are notification messages that are targeted to all the devices that are subscribed to a particular tag.

Tags represent topics of interest to the user and provide the ability to receive notifications according to the chosen interest.

Broadcast notifications are a form of tag push notifications that are targeted to all subscribed devices. Broadcast notifications are enabled by default for any push-enabled MobileFirst application by a subscription to a reserved Push.all tag (auto-created for every device). Broadcast notifications can be disabled by by unsubscribing from the reserved Push.all tag.

Agenda

- Notifications configuration
- Notifications API
- Sample application

Notifications configuration

Tag Notifications configuration

Setting up tags

Tags are defined in the application-descriptor.xml file:

```
<nativeAndroidApp xmlns="http://www.worklight.com/native-android-descriptor" id="NativeAndroidTagNoti
 1
 2
     <pushSender key="API_KEY" senderId="PROJECT_NUMBER"/>
 3
 4
     ...
 5
 6
     <tags>>
 7
       <tag>
 8
          <name>my tag 1</name>
 9
          <description>About my tag 1</description>
10
       </tag>
11
       <tag>
12
          <name>my tag 2</name>
13
          <description>About my tag 2</description>
14
       </tag>
15
     </tags>
                                                                                                      M
```

Notifications API

API methods for tag notifications

Client-side API

- WLPush.subscribeTag(tagName,options) Subscribes the device to the specified tag name
- WLPush.unsubscribeTag(tagName,options) Unsubscribes the device from the specified tag
 name
- WLPush.isTagSubscribed(tagName) Returns whether the device is subscribed to a specified tag name

Common API methods for tag and broadcast notifications

Client-side API

- WLNotificationListener
 Defines the callback method to be notified when the notification arrives.
- client.getPush().setWLNotificationListener(listener)
 This method sets the implementation class of the WLNotificationListener interface.
- client.getPush().setOnReadyToSubscribeListener(listener)
 This method registers a listener to be used for push notifications. This listener should implement the onReadyToSubscribe() method.
- The onMessage(props,payload) method of WLNotificationListener is called when a push notification is received by the device.
 - **props** A JSON block that contains the notifications properties of the platform.
 - payload A JSON block that contains other data that is sent from MobileFirst Server. The
 JSON block also contains the tag name for tag-based or broadcast notification. The tag name
 appears in the "tag" element. For broadcast notification, the default tag name is Push.ALL.

WL.Server.sendMessage(applicationId, notificationOptions)
This method submits a notification that is based on the specified target parameters.

- applicationId (mandatory) The name of the MobileFirst application
- notificationOptions (mandatory) A JSON block containing message properties

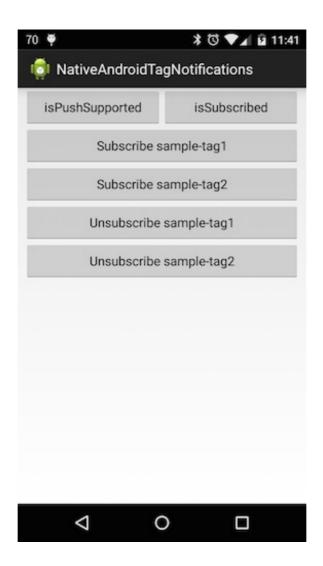

For a full list of message properties, refer to the WL.Server.sendMessage API in the API reference of user documentation

Sample application

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/TagNotifications) the MobileFirst project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/TagNotificationsAndroid) the Native project.

- The TagNotifications project contains a MobileFirst native API that you can deploy to your MobileFirst Server instance.
- The TagNotificationsAndroid project contains a native android application that uses a MobileFirst native API library to subscribe to push notifications and receive notifications from GCM.
- Make sure to update the wlclient.properties file in the native project with the relevant server settings.

Sending a notification

To test the application is able to receive a push notification you can perform one of the following:

- 1. From MobileFirst Studio, right-click the adapter folder, select Call MobileFirst Adapter and:
 - If selecting the "sendBroadcastNotification" procedure, provide the application ID and notification text in quotation marks.
 - If selecting the "sendTagNotification" procedure, provide the application ID, notification text and tag name in quotation marks.
 - The application ID can be determined from the id attribute in applicationdescriptor.xml:

```
1 <application ... id="NativeAndroidTagNotifications" ...>
```

2. If using the CLI:

```
$ mfp adapter call
[?] Which endpoint do you want to use? PushAdapter/sendBroadcastNotification
[?] Enter the comma-separated parameters: "NativeAndroidTagNotifications", "hel
[?] How should the procedure be called? GET
```

Or:

```
$ mfp adapter call
[?] Which endpoint do you want to use? PushAdapter/sendTagNotification<
[?] Enter the comma-separated parameters: "NativeAndroidTagNotifications", "hel
[?] How should the procedure be called? GET</pre>
```
