Implementing the challenge handler in Android applications

Overview

Prerequisite: Make sure to read the **CredentialsValidationSecurityCheck** challenge handler implementation (../../credentials-validation/android) tutorial.

The challenge handler tutorial demonstrates a few additional features (APIs) such as preemptive login, logout, and obtainAccessToken.

Login

In this example, UserLogin expects *key:value*s called username and password. Optionally, it also accepts a Boolean rememberMe key, which tells the security check to remember this user for a longer period. In the sample application, this is collected using a Boolean value from a checkbox in the login form.

The credentials argument is a JSONObject containing username, password, and rememberMe:

```
submitChallengeAnswer(credentials);
```

You might also want to log in a user without any challenge being received. For example, you can show a login screen as the first screen of the application, or show a login screen after a logout, or a login failure. Those scenarios are called **preemptive logins**.

You cannot call the submitChallengeAnswer API if there is no challenge to answer. For those scenarios, the MobileFirst Foundation SDK includes the login API:

```
WLAuthorizationManager.getInstance().login(securityCheckName, credentials, new WLLoginResponseListener() {
    @Override
    public void onSuccess() {
        Log.d(securityCheckName, "Login Preemptive Success");
    }

@Override
    public void onFailure(WLFailResponse wlFailResponse) {
        Log.d(securityCheckName, "Login Preemptive Failure");
    }
});
```

If the credentials are wrong, the security check sends back a challenge.

It is the developer's responsibility to know when to use <code>login</code>, as opposed to <code>submitChallengeAnswer</code>, based on the application's needs. One way to achieve this is to define a Boolean flag, for example <code>isChallenged</code>, and set it to <code>true</code> when <code>handleChallenge</code> is reached, or set it to <code>false</code> in any other cases (failure, success, initialization, etc).

When the user clicks the **Login** button, you can dynamically choose which API to use:

```
public void login(JSONObject credentials){
   if(isChallenged){
      submitChallengeAnswer(credentials);
   }
   else{
      WLAuthorizationManager.getInstance().login(securityCheckName, credentials, new WLLoginRespon seListener() {
   //...
    });
   }
}
```

Note: The WLAuthorizationManager login() API has its own onSuccess and onFailure methods, the handleSuccess or handleFailure methods of the relevant challenge handler are **also** called.

Obtaining an access token

Because this security check supports the **RememberMe** functionality (as the rememberMe Boolean key), it would be useful to check whether the client is currently logged in when the application starts.

The MobileFirst Foundation SDK provides the obtainAccessToken API to ask the server for a valid token:

```
WLAuthorizationManager.getInstance().obtainAccessToken(scope, new WLAccessTokenListener() {
    @Override
    public void onSuccess(AccessToken accessToken) {
        Log.d(securityCheckName, "auto login success");
    }

@Override
    public void onFailure(WLFailResponse wlFailResponse) {
        Log.d(securityCheckName, "auto login failure");
    }
});
```

Note: The WLAuthorizationManager obtainAccessToken() API has its own onSuccess and onFailure methods, the handleSuccess or handleFailure methods of the relevant challenge handler are **also** called.

If the client is already logged-in or is in the *remembered* state, the API triggers a success. If the client is not logged in, the security check sends back a challenge.

The obtainAccessToken API takes in a **scope**. The scope can be the name of your **security check**.

Learn more about **scopes** in the Authorization concepts (../../) tutorial

Retrieving the authenticated user

The challenge handler handleSuccess method takes a JSONObject identity as a parameter. If the security check sets an AuthenticatedUser, this object contains the user's properties. You can use handleSuccess to save the current user:

```
@Override
public void handleSuccess(JSONObject identity) {
    super.handleSuccess(identity);
    isChallenged = false;
    try {
        //Save the current user
        SharedPreferences preferences = context.getSharedPreferences(Constants.PREFERENCES_FILE,
        Context.MODE_PRIVATE);
        SharedPreferences.Editor editor = preferences.edit();
        editor.putString(Constants.PREFERENCES_KEY_USER, identity.getJSONObject("user").toString());
        editor.commit();
    } catch (JSONException e) {
        e.printStackTrace();
    }
}
```

Here, identity has a key called user which itself contains a JSONObject representing the AuthenticatedUser:

```
"user": {
  "id": "john",
  "displayName": "john",
  "authenticatedAt": 1455803338008,
  "authenticatedBy": "UserLogin"
}
}
```

Logout

The MobileFirst Foundation SDK also provides a logout API to log out from a specific security check:

```
WLAuthorizationManager.getInstance().logout(securityCheckName, new WLLogoutResponseListener() {
    @Override
    public void onSuccess() {
        Log.d(securityCheckName, "Logout Success");
    }

@Override
    public void onFailure(WLFailResponse wlFailResponse) {
        Log.d(securityCheckName, "Logout Failure");
    }
});
```

Sample applications

Two samples are associated with this tutorial:

- PreemptiveLoginAndroid: An application that always starts with a login screen, using the preemptive login API.
- **RememberMeAndroid**: An application with a *Remember Me* checkbox. The user can bypass the login screen the next time the application is opened.

Both samples use the same UserLogin security check from the **SecurityCheckAdapters** adapter Maven project.

Center/PreemptiveLoginAndroid/tree/release80) the Preemptive Login project.

Sample usage

Follow the sample's README.md file for instructions.

The username/password for the app must match, i.e. "john"/"john".
