Using JSONStore in Native Android applications

Overview

This tutorial is a continuation of the JSONStore Overview tutorial. The tutorial covers the following topics:

- Basic API Usage
- Advanced Usage
- Sample application
- Additional information

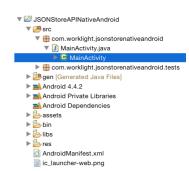

Basic API Usage

Open

Use openCollections to open one or more JSONStore collections

Starting or provisioning a collections means creating the persistent storage that contains the collection and documents, if it does not exists.

If the persistent storage is encrypted and a correct password is passed, the necessary security procedures to make the data accessible are run.

For optional features that you can enable at initialization time, see **Security, Multiple User Support,** and **MobileFirst Adapter Integration** in the second part of this module

```
Context context = getContext();

try {

JSONStoreCollection people = new JSONStoreCollection("people");

people.setSearchField("name", SearchFieldType.STRING);

people.setSearchField("age", SearchFieldType.INTEGER);

List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>()

;

collections.add(people);

WLJSONStore.getInstance(context).openCollections(collections);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Get

Use getCollectionByName to create an accessor to the collection. You must call openCollections before you call getCollectionByName.

```
Context context = getContext();
try {
    String collectionName = "people";
    JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);
    // handle success
} catch(JSONStoreException e) {
    // handle failure
}
```

The variable collection can now be used to perform operations on the people collection such as add, find, and replace

Add

Use addData to store data as documents inside a collection

```
Context context = getContext();

try {
    String collectionName = "people";
    JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collection Name);
//Add options.

JSONStoreAddOptions options = new JSONStoreAddOptions();
    options.setMarkDirty(true);
    JSONObject data = new JSONObject("{age: 23, name: 'yoel'}")
    collection.addData(data, options);
    // handle success
} catch(JSONStoreException e) {
    // handle failure
}
```

Find

Use findDocuments to locate a document inside a collection by using a query. Use findAllDocuments to retrieve all the documents inside a collection. Use findDocumentById to search by the document unique identifier.

```
Context context = getContext();
try {
  String collectionName = "people";
  JSONStoreQueryPart queryPart = new JSONStoreQueryPart();
  // fuzzy search LIKE
  queryPart.addLike("name", name);
  JSONStoreQueryParts query = new JSONStoreQueryParts();
  query.addQueryPart(queryPart);
  JSONStoreFindOptions options = new JSONStoreFindOptions();
  // returns a maximum of 10 documents, default: returns every document
  options.setLimit(10);
  JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collection
  List<JSONObject> results = collection.findDocuments(query, options);
    // handle success
} catch(JSONStoreException e) {
  // handle failure
}
```

Replace

Use replaceDocument to modify documents inside a collection. The field that you use to perform the replacement is id, the document unique identifier.

```
Context context = getContext();

try {
    String collectionName = "people";
    JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collection Name);
    JSONStoreReplaceOptions options = new JSONStoreReplaceOptions();
    // mark data as dirty
    options.setMarkDirty(true);
    JSONStore replacement = new JSONObject("{_id: 1, json: {age: 23, name: 'chevy'}}");
    collection.replaceDocument(replacement, options)
    // handle success
} catch(JSONStoreException e) {
    // handle failure
}
```

This examples assumes that the document $\{ \underline{id} : 1, json : \{ name : 'yoel', age : 23 \} \}$ is in the collection

Remove

Use removeDocumentById to delete a document from a collection.

Documents are not erased from the collection until you call markDocumentClean. For more information, see the **MobileFirst Adapter Integration** section later in this tutorial

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);

JSONStoreRemoveOptions options = new JSONStoreRemoveOptions();

// Mark data as dirty

options.setMarkDirty(true);

collection.removeDocumentById(1, options);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Remove Collection

Use removeCollection to delete all the documents that are stored inside a collection. This operation is similar to dropping a table in database terms

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collection Name);

collection.removeCollection();

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Destroy

Use destroy to remove the following data:

- All documents
- All collections
- All Stores "See Multiple User Support later in this tutorial"
- All JSONStore metadata and security artifacts "See Security later in this tutorial"

```
Context context = getContext();
try {
    WLJSONStore.getInstance(context).destroy()
;
    // handle success
} catch(JSONStoreException e) {
    // handle failure
}
```

Advanced Usage

Security

You can secure all the collections in a store by passing a <code>JSONStoreInitOptions</code> object with a password to the <code>openCollections</code> function. If no password is passed, the documents of all the collections in the store are not encrypted.

Some security metadata is stored in shared preferences (Android);

The store is encrypted with a 256-bit Advanced Encryption Standard (AES) key. All keys are strengthened with Password-Based Key Derivation Function 2 (PBKDF2).

Use closeAll to lock access to all the collections until you call openCollections again. If you think of openCollections as a login function you can think of closeAll as the corresponding logout function.

Use changePassword to change the password.

```
Context context = getContext();

try {

JSONStoreCollection people = new JSONStoreCollection("people");

people.setSearchField("name", SearchFieldType.STRING);

people.setSearchField("age", SearchFieldType.INTEGER);

List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();

collections.add(people);

JSONStoreInitOptions options = new JSONStoreInitOptions();

options.setPassword("123");

WLJSONStore.getInstance(context).openCollections(collections, options);

// handle success

} catch(JSONStoreException e) {

// handle failure
}
```

Multiple User Support

You can create multiple stores that contain different collections in a single MobileFirst application. The openCollections function can take an options object with a username. If no username is given, the default username is **jsonstore**

```
Context context = getContext();

try {

JSONStoreCollection people = new JSONStoreCollection("people");

people.setSearchField("name", SearchFieldType.STRING);

people.setSearchField("age", SearchFieldType.INTEGER);

List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();

collections.add(people);

JSONStoreInitOptions options = new JSONStoreInitOptions();

options.setUsername("yoel");

WLJSONStore.getInstance(context).openCollections(collections, options);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

MobileFirst Adapter Integration

This section assumes that you are familiar with MobileFirst adapters. MobileFirst Adapter Integration is optional and provides ways to send data from a collection to an adapter and get data from an adapter into a collection.

You can achieve these goals by using functions such as WLClient.invokeProcedure or your own instance of an HttpClient if you need more flexibility.

Adapter Implementation

Create a MobileFirst adapter and name it "**People**". Define it's procedures addPerson, getPeople, pushPeople, removePerson, and replacePerson.

```
function getPeople() {
var data = { peopleList : [{name: 'chevy', age: 23}, {name: 'yoel', age: 23}] };
WL.Logger.debug('Adapter: people, procedure: getPeople called.');
WL.Logger.debug('Sending data: ' + JSON.stringify(data));
return data:
}
function pushPeople(data) {
WL.Logger.debug('Adapter: people, procedure: pushPeople called.');
WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
return:
}
function addPerson(data) {
WL.Logger.debug('Adapter: people, procedure: addPerson called.');
WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
return;
}
function removePerson(data) {
WL.Logger.debug('Adapter: people, procedure: removePerson called.');
WL.Logger.debug('Got data from JSONStore to REMOVE: ' + data);
return;
function replacePerson(data) {
WL.Logger.debug('Adapter: people, procedure: replacePerson called.');
WL.Logger.debug('Got data from JSONStore to REPLACE: ' + data);
return;
}
```

Load data from MobileFirst Adapter

To load data from a MobileFirst Adapter use WLClient.invokeProcedure.

```
WLResponseListener responseListener = new WLResponseListener() {
  @Override
  public void onFailure(final WLFailResponse response) {
    // handle failure
  }
  @Override
  public void onSuccess(WLResponse response) {
       JSONArray loadedDocuments = response.getResponseJSON().getJSONArray("peopleList");
    } catch(Exception e) {
      // error decoding JSON data
    }
  }
};
WLProcedureInvocationData invocationData = new WLProcedureInvocationData("People", "getPeople");
Context context = getContext();
WLClient client = WLClient.createInstance(context);
client.invokeProcedure(invocationData, responseListener);
```

Calling findAllDirtyDocuments returns and array of so called "dirty documents", which are documents that have local modifications that do not exist on the back-end system.

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collection Name);

List<JSONObject> dirtyDocs = collection.findAllDirtyDocuments();

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

To prevent JSONStore from marking the documents as "dirty", pass the option options.setMarkDirty(false) to add, replace, and remove

Push changes

To push changes to a MobileFirst adapter, call the findAllDirtyDocuments to get a list of documents with modifications and then use WLClient.invokeProcedure. After the data is sent and a successful response is received make sure you call markDocumentsClean.

```
WLResponseListener responseListener = new WLResponseListener() {
  @Override
  public void onFailure(final WLFailResponse response) {
    // handle failure
  @Override
  public void onSuccess(WLResponse response) {
    // handle success
  }
};
Context context = getContext();
WLClient client = WLClient.createInstance(context);
  String collectionName = "people";
  JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collection
Name);
  List<JSONObject> dirtyDocuments = people.findAllDirtyDocuments();
  WLProcedureInvocationData invocationData = new WLProcedureInvocationData("People", "pushPeo
ple");
  invocationData.setParameters(new Object[]{dirtyDocuments});
  client.invokeProcedure(invocationData, responseListener);
} catch(JSONStoreException e) {
  // handle failure
}
```

Sample application

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/JSONStore/tree/release71) the MobileFirst project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/JSONStoreAndroid/tree/release71) the Native project.

The Native Android project contains an application that demonstrates the use of JSONStore.

Additional information

For more information about JSONStore, see the product user documentation.
