Native iOS applications

Overview

This tutorial is a continuation of the JSONStore Overview tutorial.

Jump to:

- Adding JSONStore
- Basic Usage
- Advanced Usage
- Sample application

Adding JSONStore

Adding the JSONStore component to native iOS applications is accomplished using CocoaPods. First, make sure the MobileFirst Native SDK is present by following the instructions in the tutorial: Configuring a Native iOS Application with the MobileFirst Platform SDK (../configuring-the-mfpf-sdk/configuring-a-native-ios-application-with-the-mfp-sdk/).

Next, perform the following steps:

1. Edit the existing podfile, located at the root of the Xcode project. Add to the file:

```
source 'https://github.com/CocoaPods/Specs.git'
pod 'IBMMobileFirstPlatformFoundationJSONStore'
```

2. From a **Command-line** window, navigate to the root of the Xcode project and run the command: pod install - note that this action may take a while.

The JSONStore feature should now be available to you in the Xcode project.

Basic Usage

Open

Use openCollections to open one or more JSONStore collections.

Starting or provisioning a collections means creating the persistent storage that contains the collection and documents, if it does not exists.

If the persistent storage is encrypted and a correct password is passed, the necessary security procedures to make the data accessible are run.

For optional features that you can enable at initialization time, see **Security, Multiple User Support** and **MobileFirst Adapter Integration** in the second part of this tutorial.

```
NSError *error = nil;

JSONStoreCollection* collection = [[JSONStoreCollection alloc] initWithName:@"p
eople"];
[collection setSearchField:@"name" withType:JSONStore_String];
[collection setSearchField:@"age" withType:JSONStore_Integer];

[[JSONStore sharedInstance] openCollections:@[collection] withOptions:nil error
:error];
```

Get

Use getCollectionWithName to create an accessor to the collection. You must call openCollections before you call getCollectionWithName.

```
NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];
```

The variable collection can now be used to perform operations on the people collection such as add, find, and replace.

Add

Use addData to store data as documents inside a collection.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];

NSDictionary *data = @{@"name" : @"yoel", @"age" : @23};
[[collection addData:@[data] andMarkDirty:YES withOptions:nil error:error] intV
alue];
```

Find

Use findWithQueryParts to locate a document inside a collection by using a query. Use findAllWithOptions to retrieve all the documents inside a collection. Use findWithIds to search by the document unique identifier.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith Name:collectionName];
//Build a query part.

JSONStoreQueryPart *query = [[JSONStoreQueryPart alloc] init];
[query searchField:@"name" like:@"yoel"];
JSONStoreQueryOptions *options = [[JSONStoreQueryOptions alloc] init];

// returns a maximum of 10 documents, default: returns every document
[options setLimit:@10];

// Count using the query part built above.
NSArray *results = [collection findWithQueryParts:@[query] andOptions:options e rror:error];
```

Replace

Use replaceDocuments to modify documents inside a collection. The field that you use to perform the replacement is id, the document unique identifier.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];

//Replacing name 'carlos' with name 'carlitos'.<br />
NSDictionary *replacement = @{@"_id": @1, @"json" : @{@"name" : @"chevy", @"age" : @23}};
[collection replaceDocuments:@[replacement] andMarkDirty:YES error:error];
```

This examples assumes that the document $\{ id: 1, json: \{name: 'yoel', age: 23\} \}$ is in the collection.

Remove

Use removeWithIds to delete a document from a collection. Documents are not erased from the collection until you call markDocumentClean. For more information, see the **MobileFirst Adapter Integration** section later in this tutorial.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];
[collection removeWithIds:@[@1] andMarkDirty:YES error:error];
```

Remove Collection

Use removeCollectionWithError to delete all the documents that are stored inside a collection. This operation is similar to dropping a table in database terms.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];
BOOL removeCollectionWorked = [collection removeCollectionWithError:error];
```

Destroy

Use destroyDataAndReturnError to remove the following data:

- All documents
- All collections
- All Stores See Multiple User Support later in this tutorial
- All JSONStore metadata and security artifacts See Security later in this tutorial

```
NSError *error = nil;
[[JSONStore sharedInstance] destroyDataAndReturnError:error];
```

Advanced Usage

Security

You can secure all the collections in a store by passing a JSONStoreOpenOptions object with a password to the openCollections function. If no password is passed, the documents of all the collections in the store are not encrypted.

Some security metadata is stored in the keychain (iOS).

The store is encrypted with a 256-bit Advanced Encryption Standard (AES) key. All keys are strengthened with Password-Based Key Derivation Function 2 (PBKDF2).

Use closeAllCollectionsAndReturnError to lock access to all the collections until you call openCollections again. If you think of openCollections as a login function you can think of closeAllCollectionsAndReturnError as the corresponding logout function.

Use changeCurrentPassword to change the password.

```
NSError *error = nil;

JSONStoreCollection *collection = [[JSONStoreCollection alloc] initWithName:@"p
eople"];
[collection setSearchField:@"name" withType:JSONStore_String];
[collection setSearchField:@"age" withType:JSONStore_Integer];

JSONStoreOpenOptions *options = [JSONStoreOpenOptions new];
[options setPassword:@"123"];
[[JSONStore sharedInstance] openCollections:@[collection] withOptions:options e
rror:error];
```

Multiple User Support

You can create multiple stores that contain different collections in a single MobileFirst application. The openCollections function can take an options object with a username. If no username is given, the default username is "jsonstore".

```
NSError *error = nil;

JSONStoreCollection *collection = [[JSONStoreCollection alloc] initWithName:@"p
eople"];
[collection setSearchField:@"name" withType:JSONStore_String];
[collection setSearchField:@"age" withType:JSONStore_Integer];

JSONStoreOpenOptions *options = [JSONStoreOpenOptions new];
[options setUsername:@"yoel"];
[[JSONStore sharedInstance] openCollections:@[collection] withOptions:options e
rror:error];
```

MobileFirst Adapter Integration

This section assumes that you are familiar with MobileFirst adapters. MobileFirst Adapter Integration is optional and provides ways to send data from a collection to an adapter and get data from an adapter into a collection.

You can achieve these goals by using functions such as WLClient invokeProcedure or your own instance of an NSURLConnection if you need more flexibility.

Adapter Implementation

Create a MobileFirst adapter and name it "**People**". Define it's procedures addPerson, getPeople, pushPeople, removePerson, and replacePerson.

```
function getPeople() {
   var data = { peopleList : [{name: 'chevy', age: 23}, {name: 'yoel', age: 23}
}] };
   WL.Logger.debug('Adapter: people, procedure: getPeople called.');
   WL.Logger.debug('Sending data: ' + JSON.stringify(data));
   return data;
}
function pushPeople(data) {
   WL.Logger.debug('Adapter: people, procedure: pushPeople called.');
   WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
    return;
}
function addPerson(data) {
   WL.Logger.debug('Adapter: people, procedure: addPerson called.');
   WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
    return;
}
function removePerson(data) {
   WL.Logger.debug('Adapter: people, procedure: removePerson called.');
   WL.Logger.debug('Got data from JSONStore to REMOVE: ' + data);
    return;
}
function replacePerson(data) {
   WL.Logger.debug('Adapter: people, procedure: replacePerson called.');
   WL.Logger.debug('Got data from JSONStore to REPLACE: ' + data);
   return;
}
```

Load data from MobileFirst Adapter

To load data from a MobileFirst Adapter use WLClient invokeProcedure.

```
// Start - LoadFromAdapter
@interface LoadFromAdapter : NSObject<WLDelegate>
@end
@implementation LoadFromAdapter
- (void) onSuccess: (WLResponse *) response {
  NSArray *loadedDocuments = [[response getResponseJson] objectForKey:@"people
List"];
  // handle success
}
-(void)onFailure:(WLFailResponse *)response {
  // handle success
}
@end
// End - LoadFromAdapter
NSError *error = nil;
WLProcedureInvocationData *invocationData = [[WLProcedureInvocationData alloc]
initWithAdapterName:@"People" procedureName:@"getPeople"];
LoadFromAdapter *loadDelegate = [[LoadFromAdapter alloc] init];
WLClient *client = [[WLClient sharedInstance] init];
[client invokeProcedure:invocationData withDelegate:loadDelegate];
```

Get Push Required (Dirty Documents)

Calling allDirtyAndReturnError returns and array of so called "dirty documents", which are documents that have local modifications that do not exist on the back-end system.

```
NSError* error = nil;
NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];
NSArray *dirtyDocs = [collection allDirtyAndReturnError:error];
```

To prevent JSONStore from marking the documents as "dirty", pass the option andMarkDirty:N0 to add, replace, and remove.

Push changes

To push changes to a MobileFirst adapter, call the findAllDirtyDocuments to get a list of documents with modifications and then use WLClient invokeProcedure. After the data is sent and a successful response is received make sure you call markDocumentsClean.

```
// Start - PushToAdapter
@interface PushToAdapter :NSObject<WLDelegate>
@end
@implementation PushToAdapter
- (void) onSuccess: (WLResponse *) response {
  // handle success
}
-(void)onFailure:(WLFailResponse *)response {
  // handle faiure
}
@end
// End - PushToAdapter
NSError* error = nil;
NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWith
Name:collectionName];
NSArray *dirtyDocs = [collection allDirtyAndReturnError:error];
WLProcedureInvocationData *invocationData = [[WLProcedureInvocationData alloc]
initWithAdapterName:@"People" procedureName:@"pushPeople"];
[invocationData setParameters:@[dirtyDocs]];
PushToAdapter *pushDelegate = [[PushToAdapter alloc] init];
WLClient *client = [[WLClient sharedInstance] init];
[client invokeProcedure:invocationData withDelegate:pushDelegate];
```
