JSONStore in Android applications

Overview

IBM MobileFirst Platform Foundation's **JSONStore** is an optional client-side API providing a lightweight, document-oriented storage system. JSONStore enables persistent storage of **JSON documents**. Documents in an application are available in JSONStore even when the device that is running the application is offline. This persistent, always-available storage can be useful to give users access to documents when, for example, there is no network connection available in the device.

Key features

- Data indexing for efficient searching
- Data encryption in production environments
- Mechanism for tracking local-only changes to the stored data
- Support for multiple users

Note: Some features such as data encryption are beyond the scope of this tutorial. All features are documented in detail in the IBM MobileFirst Platform Foundation user documentation website.

Prerequisite: Make sure the MobileFirst Native SDK was added to the Android Studio project. Follow the Adding the MobileFirst Platform Foundation SDK to iOS applications (../../adding-the-mfpf-sdk/android/) tutorial.

Jump to:

- Adding JSONStore
- Basic Usage
- Advanced Usage
- Sample application

Adding JSONStore

- 1. In Android → Gradle Scripts, select the build.gradle (Module: app) file.
- 2. Add the following to the existing in dependencies section:

compile 'com.ibm.mobile.foundation:ibmmobilefirstplatformfoundationjsonstore:8.0.0-SNAPSHOT'

Basic Usage

Open

Use openCollections to open one or more JSONStore collections.

Starting or provisioning a collections means creating the persistent storage that contains the collection and documents, if it does not exists. If the persistent storage is encrypted and a correct password is passed, the necessary security procedures to make the data accessible are run.

For optional features that you can enable at initialization time, see **Security, Multiple User Support** and **MobileFirst Adapter Integration** in the second part of this tutorial.

```
Context context = getContext();

try {

JSONStoreCollection people = new JSONStoreCollection("people");

people.setSearchField("name", SearchFieldType.STRING);

people.setSearchField("age", SearchFieldType.INTEGER);

List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();

collections.add(people);

WLJSONStore.getInstance(context).openCollections(collections);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Get

Use getCollectionByName to create an accessor to the collection. You must call openCollections before you call getCollectionByName.

```
Context context = getContext();

try {
String collectionName = "people";
JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);
// handle success
} catch(JSONStoreException e) {
// handle failure
}
```

The variable collection can now be used to perform operations on the people collection such as add, find, and replace

Add

Use addData to store data as documents inside a collection

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);

//Add options.

JSONStoreAddOptions options = new JSONStoreAddOptions();

options.setMarkDirty(true);

JSONObject data = new JSONObject("{age: 23, name: 'yoel'}")

collection.addData(data, options);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Find

Use findDocuments to locate a document inside a collection by using a query. Use findAllDocuments to retrieve all the documents inside a collection. Use findDocumentById to search by the document unique identifier.

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreQueryPart queryPart = new JSONStoreQueryPart();

// fuzzy search LIKE

queryPart.addLike("name", name);

JSONStoreQueryParts query = new JSONStoreQueryParts();

query.addQueryPart(queryPart);

JSONStoreFindOptions options = new JSONStoreFindOptions();

// returns a maximum of 10 documents, default: returns every document

options.setLimit(10);

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);

List<JSONObject> results = collection.findDocuments(query, options);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Replace

Use replaceDocument to modify documents inside a collection. The field that you use to perform the replacement is id, the document unique identifier.

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);

JSONStoreReplaceOptions options = new JSONStoreReplaceOptions();

// mark data as dirty

options.setMarkDirty(true);

JSONStore replacement = new JSONObject("{_id: 1, json: {age: 23, name: 'chevy'}}");

collection.replaceDocument(replacement, options);

// handle success

} catch(JSONStoreException e) {

// handle failure
}
```

This examples assumes that the document $\{ \underline{id} : 1, json : \{ name : 'yoel', age : 23 \} \}$ is in the collection.

Remove

Use removeDocumentById to delete a document from a collection. Documents are not erased from the collection until you call markDocumentClean. For more information, see the **MobileFirst Adapter Integration** section later in this tutorial.

```
Context context = getContext();

try {
    String collectionName = "people";
    JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);
    JSONStoreRemoveOptions options = new JSONStoreRemoveOptions();

// Mark data as dirty
    options.setMarkDirty(true);
    collection.removeDocumentById(1, options);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Remove Collection

Use removeCollection to delete all the documents that are stored inside a collection. This operation is similar to dropping a table in database terms.

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);

collection.removeCollection();

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Destroy

Use destroy to remove the following data:

- All documents
- All collections
- All Stores See Multiple User Support later in this tutorial
- All JSONStore metadata and security artifacts See Security later in this tutorial

```
Context context = getContext();
try {
  WLJSONStore.getInstance(context).destroy();
  // handle success
} catch(JSONStoreException e) {
  // handle failure
}
```

Advanced Usage

Security

You can secure all the collections in a store by passing a <code>JSONStoreInitOptions</code> object with a password to the <code>openCollections</code> function. If no password is passed, the documents of all the collections in the store are not encrypted.

Some security metadata is stored in the shared preferences (Android).

The store is encrypted with a 256-bit Advanced Encryption Standard (AES) key. All keys are strengthened with Password-Based Key Derivation Function 2 (PBKDF2).

Use closeAll to lock access to all the collections until you call openCollections again. If you think of openCollections as a login function you can think of closeAll as the corresponding logout function.

Use changePassword to change the password.

```
Context context = getContext();

try {

JSONStoreCollection people = new JSONStoreCollection("people");

people.setSearchField("name", SearchFieldType.STRING);

people.setSearchField("age", SearchFieldType.INTEGER);

List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();

collections.add(people);

JSONStoreInitOptions options = new JSONStoreInitOptions();

options.setPassword("123");

WLJSONStore.getInstance(context).openCollections(collections, options);

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

Multiple User Support

You can create multiple stores that contain different collections in a single MobileFirst application. The openCollections function can take an options object with a username. If no username is given, the default username is ""jsonstore".

```
Context context = getContext();

try {

JSONStoreCollection people = new JSONStoreCollection("people");

people.setSearchField("name", SearchFieldType.STRING);

people.setSearchField("age", SearchFieldType.INTEGER);

List<JSONStoreCollection> collections = new LinkedList<JSONStoreCollection>();

collections.add(people);

JSONStoreInitOptions options = new JSONStoreInitOptions();

options.setUsername("yoel");

WLJSONStore.getInstance(context).openCollections(collections, options);

// handle success

} catch(JSONStoreException e) {

// handle failure
}
```

MobileFirst Adapter Integration

This section assumes that you are familiar with MobileFirst adapters. MobileFirst Adapter Integration is optional and provides ways to send data from a collection to an adapter and get data from an adapter into a collection. You can achieve these goals by using functions such as WLResourceRequest or your own instance of an HttpClient if you need more flexibility.

Adapter Implementation

Create a MobileFirst adapter and name it "**JSONStoreAdapter**". Define it's procedures addPerson, getPeople, pushPeople, removePerson, and replacePerson.

```
function getPeople() {
  var data = { peopleList : [{name: 'chevy', age: 23}, {name: 'yoel', age: 23}] };
  WL.Logger.debug('Adapter: people, procedure: getPeople called.');
  WL.Logger.debug('Sending data: ' + JSON.stringify(data));
  return data;
function pushPeople(data) {
  WL.Logger.debug('Adapter: people, procedure: pushPeople called.');
  WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
  return:
}
function addPerson(data) {
  WL.Logger.debug('Adapter: people, procedure: addPerson called.');
  WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
  return;
}
function removePerson(data) {
  WL.Logger.debug('Adapter: people, procedure: removePerson called.');
  WL.Logger.debug('Got data from JSONStore to REMOVE: ' + data);
  return;
function replacePerson(data) {
  WL.Logger.debug('Adapter: people, procedure: replacePerson called.');
  WL.Logger.debug('Got data from JSONStore to REPLACE: ' + data);
  return;
}
```

Load data from MobileFirst Adapter

To load data from a MobileFirst Adapter use WLResourceRequest.

```
WLResponseListener responseListener = new WLResponseListener() {
 @Override
 public void onFailure(final WLFailResponse response) {
  // handle failure
 }
 @Override
 public void onSuccess(WLResponse response) {
  try {
   JSONArray loadedDocuments = response.getResponseJSON().getJSONArray("peopleList");
  } catch(Exception e) {
   // error decoding JSON data
  }
 }
};
 WLResourceRequest request = new WLResourceRequest(new URI("/adapters/JSONStoreAdapter/getP
eople"), WLResourceRequest.GET);
 request.send(responseListener);
} catch (URISyntaxException e) {
 // handle error
}
```

Get Push Required (Dirty Documents)

Calling findAllDirtyDocuments returns and array of so called "dirty documents", which are documents that have local modifications that do not exist on the back-end system.

```
Context context = getContext();

try {

String collectionName = "people";

JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionName);

List<JSONObject> dirtyDocs = collection.findAllDirtyDocuments();

// handle success
} catch(JSONStoreException e) {

// handle failure
}
```

To prevent JSONStore from marking the documents as "dirty", pass the option options.setMarkDirty(false) to add, replace, and remove.

Push changes

To push changes to a MobileFirst adapter, call the findAllDirtyDocuments to get a list of documents with modifications and then use WLResourceRequest. After the data is sent and a successful response is received make sure you call markDocumentsClean.

```
WLResponseListener responseListener = new WLResponseListener() {
 @Override
 public void onFailure(final WLFailResponse response) {
  // handle failure
 }
 @Override
 public void onSuccess(WLResponse response) {
  // handle success
 }
};
Context context = getContext();
try {
 String collectionName = "people";
 JSONStoreCollection collection = WLJSONStore.getInstance(context).getCollectionByName(collectionN
 List<JSONObject> dirtyDocuments = people.findAllDirtyDocuments();
 JSONObject payload = new JSONObject();
 payload.put("people", dirtyDocuments);
 WLResourceRequest request = new WLResourceRequest(new URI("/adapters/JSONStoreAdapter/push
People"), WLResourceRequest.POST);
 request.send(payload, responseListener);
} catch(JSONStoreException e) {
 // handle failure
} catch (URISyntaxException e) {
 // handle error
}
```

Sample application

The JSONStoreAndroid project contains a native Android application that utilizes the JSONStore API set. Included is a JavaScript adapter Maven project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/JSONStoreAndroid) the Native Android project. Click to download (https://github.com/MobileFirst-Platform-Developer-Center/JSONStoreAdapter/tree/release80) the adapter Maven project.

Sample usage

- 1. From the command line, navigate to the project's root folder.
- 2. Ensure the sample is registered in the MobileFirst Server by running the command: mfpdev app register.
- 3. The sample uses the JSONStoreAdapter contained in the Adapters Maven project. Use either Maven or MobileFirst Developer CLI to build and deploy the adapter (../../adapters/creating-adapters/).
- 4. Import the project to Android Studio, and run the sample by clicking the **Run** button.
