Implementing the challenge handler in Android applications

fork and edit tutorial (https://github.ibm.com/MFPSamples/DevCenter/tree/master/tutorials/en/foundation/8.0/authentication-and-security/user-authentication/android/index.md) | report issue (https://github.ibm.com/MFPSamples/DevCenter/issues/new)

Overview

Prerequisite: This tutorial is a continuation of the **CredentialsValidationSecurityCheck**'s challenge handler implementation (../../credentials-validation/android) tutorial. Make sure to read it first.

The challenge handler implementation will be modified to fit the UserLoginSecurityCheck created in the matching security check tutorial (../security-check), and will demonstrate a few additional features (APIs) such as the preemptive login, logout and obtainAccessToken.

Creating the challenge handler

1. Create a Java class that extends | WLChallengeHandler :

```
public class UserLoginChallengeHandler extends WLChallengeHandler {
```

2. Add a constructor method:

```
public UserLoginChallengeHandler(String securityCheck) {
    super(securityCheck);
}
```

3. Register the challenge handler:

```
WLClient client = WLClient.createInstance(this);
client.registerChallengeHandler(myUserLoginChallengeHandler);
```

Handling the challenge

In this example, the challenge sent by UserLoginSecurityCheck is the same one sent by PinCodeAttempts: the number of remaining attempts to login (remainingAttempts), and an optional errorMsg. The handleChallenge method is responsible for collecting the username and password from the user.

Submitting the credentials

Once the credentials have been collected, use the WLChallengeHandler's submitChallengeAnswer(JS0N0bject answer) method to send an answer back to the security check. In this example, UserLoginSecurityCheck expects key:values called username and password. Optionally, it also accepts a boolean rememberMe key that will tell the security check to remember this user for a longer period. In the sample application, this is collected using a boolean value from a checkbox in the login form.

credentials is a JSONObject containing username, password and rememberMe:

```
submitChallengeAnswer(credentials);
```

You may also want to login a user without any challenge being received. For examples, showing a login screen as the first screen of the application, or showing a login screen after a logout, or a login failure. We call those scenarios **preemptive logins**.

You cannot call the submitChallengeAnswer API if there is no challenge to answer. For those scenarios, the MobileFirst Platform Foundation SDK includes a different API:

```
WLAuthorizationManager.getInstance().login(securityCheckName, credentials, new WLLoginResponseListe ner() {
    @Override
    public void onSuccess() {
        Log.d(securityCheckName, "Login Preemptive Success");
    }

@Override
    public void onFailure(WLFailResponse wlFailResponse) {
        Log.d(securityCheckName, "Login Preemptive Failure");
    }
});
```

If the credentials are wrong, the security check will send back a challenge.

It is the developer's responsibility to know when to use <code>login</code> vs <code>submitChallengeAnswer</code> based on the application's needs. One way to achieve this is to define a boolean flag, for example <code>isChallenged</code>, and set it to <code>true</code> when reaching <code>handleChallenge</code> or set it to <code>false</code> in any other cases (failure, success, initializing, etc).

When the user clicks the **Login** button, you can dynamically choose which API to use:

```
public void login(JSONObject credentials){
  if(isChallenged){
     submitChallengeAnswer(credentials);
  }
  else{
     WLAuthorizationManager.getInstance().login(securityCheckName, credentials, new WLLoginRespons
eListener() {
       @Override
       public void onSuccess() {
         Log.d(securityCheckName, "Login Preemptive Success");
       }
       @Override
       public void onFailure(WLFailResponse wlFailResponse) {
         Log.d(securityCheckName, "Login Preemptive Failure");
    });
  }
}
```

Obtaining an access token

Since this security check supports *remember me* functionality, it would be useful to check if the user is currently logged in, during the application startup.

The MobileFirst Platform Foundation SDK provides an API to ask the server for a valid token:

```
WLAuthorizationManager.getInstance().obtainAccessToken(scope, new WLAccessTokenListener() {
    @Override
    public void onSuccess(AccessToken accessToken) {
        Log.d(securityCheckName, "auto login success");
    }

@Override
    public void onFailure(WLFailResponse wlFailResponse) {
        Log.d(securityCheckName, "auto login failure");
    }
});
```

If the user is already logged-in or is in the *remembered* state, the API will trigger a success. If the user is not logged in, the security check will send back a challenge.

The obtainAccessToken API takes in a **scope**. The scope here can be the name of your **security check**.

Learn more about **scope** here: Authorization concepts (../../authorization-concepts)

Handling success and failure

As noted in the **CredentialsValidationSecurityCheck**'s challenge handler implementation (../../credentials-validation/android) tutorial, WLChallengeHandler will call the handleSuccess or handleFailure methods upon success or failure of the challenge. You can choose to update your UI based on those events.

Notes:

- WLAuthorizationManager's login() API has its own onSuccess and onFailure methods, the relevant challenge handler's handleSuccess or handleFailure will **also** be called.
- WLAuthorizationManager's obtainAccessToken() API has its own onSuccess and onFailure methods, the relevant challenge handler's handleSuccess or handleFailure will **also** be called.

Retrieving the authenticated user

The challenge handler's handleSuccess method receives a JSONObject identity as a parameter. If the security check sets an AuthenticatedUser, this object will contain the user's properties. You can use handleSuccess to save the current user:

```
@Override
public void handleSuccess(JSONObject identity) {
    super.handleSuccess(identity);
    isChallenged = false;
    try {
        //Save the current user
        SharedPreferences preferences = context.getSharedPreferences(Constants.PREFERENCES_FILE, C
    ontext.MODE_PRIVATE);
        SharedPreferences.Editor editor = preferences.edit();
        editor.putString(Constants.PREFERENCES_KEY_USER, identity.getJSONObject("user").toString());
        editor.commit();
    } catch (JSONException e) {
        e.printStackTrace();
    }
}
```

Here, identity has a key called user which itself contains a JSONObject representing the AuthenticatedUser:

```
"user": {
  "id": "john",
  "displayName": "john",
  "authenticatedAt": 1455803338008,
  "authenticatedBy": "UserLoginSecurityCheck"
}
}
```

Logout

The MobileFirst Platform Foundation SDK also provides a logout API to logout from a specific security check:

```
WLAuthorizationManager.getInstance().logout(securityCheckName, new WLLogoutResponseListener() {
    @Override
    public void onSuccess() {
        Log.d(securityCheckName, "Logout Success");
    }

@Override
    public void onFailure(WLFailResponse wlFailResponse) {
        Log.d(securityCheckName, "Logout Failure");
    }
});
```

Sample applications

There are two samples associated with this tutorial:

- PreemptiveLoginAndroid: An application that always starts with a login screen, using the preemptive login API.
- **RememberMeAndroid**: An application with a *Remember Me* checkbox. The user can bypass the login screen the next time the application is opened.

Both samples use the same UserLoginSecurityCheck from the **SecurityCheckAdapters** adapter Maven project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/SecurityCheckAdapters/tree/release80) the SecurityAdapters Maven project.

Click to download (https://github.com/MobileFirst-Platform-Developer-Center/RememberMeAndroid/tree/release80) the Remember Me project. Click to download

(https://github.com/MobileFirst-Platform-Developer-Center/PreemptiveLoginAndroid/tree/release80) the Remember Me project.

Sample usage

- Use either Maven or MobileFirst Developer CLI to build and deploy the available **ResourceAdapter** and **UserLogin** adapters (../../creating-adapters/).
- Ensure the sample is registered in the MobileFirst Server by running the command: mfpdev app register from a command-line window.
- Map the accessRestricted scope to the UserLogin security check:
 - In the MobileFirst Operations Console, under Applications → PIN Code → Security → Map scope elements to security checks., add a mapping from accessRestricted to UserLogin.
 - Alternatively, from the **Command-line**, navigate to the project's root folder and run the command: mfpdev app push.

Learn more about the mfpdev app push/push commands in the Using MobileFirst Developer CLI to manage MobilefFirst artifacts (../../using-the-mfpf-sdk/using-mobilefirst-developer-cli-to-manage-mobilefirst-artifacts).
