# Tag-based notifications in native Windows 8 applications

#### **Overview**

Tag notifications are notification messages that are targeted to all subscribed devices to a particular tag. Tags represent topics of interest to the user and provide the ability to receive notifications according to the chosen interest.

### Setting up tags

Tags are defined in application-descriptor.xml:

```
1
     <nativeAndroidApp xmlns="http://www.worklight.com/native-android-descriptor" id="NativeAndroidTagNotifica
2
3
     <pushSender key="API_KEY" senderId="PROJECT_NUMBER"/>
 4
5
6
7
     <tags>
8
       <taq>
9
         <name>my tag 1</name>
10
         <description>About my tag 1</description>
11
       </tag>
12
       <tag>
13
         <name>my tag 2</name>
14
          <description>About my tag 2</description>
15
       </tag>
16
     </tags>
                                                                                                        F
```

## Tag-based notifications API methods

#### Client-side API methods:

- WLPush.subscribeTag(tagName,options) Subscribes the device to the specified tag name
- WLPush.unsubscribeTag(tagName,options) Unsubscribes the device from the specified tag name
- WLPush.isTagSubscribed(tagName) Returns whether the device is subscribed to a specified tag
   name

## Common API methods for tag-based and broadcast notifications

#### Client-side API:

- WLNotificationListener Defines the callback method to be notified when the notification arrives.
- client.getPush().setWLNotificationListener(listener) This method sets the implementation class of the WLNotificationListener interface.

- client.getPush().setOnReadyToSubscribeListener(listener) This method registers a listener to be used for push notifications. This listener should implement the onReadyToSubscribe() method.
- The onMessage(props,payload) method of WLNotificationListener is called when a push notification is received by the device.
  - **props** A JSON block that contains the notifications properties of the platform.
  - payload A JSON block that contains other data that is sent from MobileFirst Server. The JSON block also contains the tag name for tag-based or broadcast notification. The tag name appears in the "tag" element. For broadcast notification, the default tag name is Push.ALL.

#### Server-side API:

This method submits a notification that is based on the specified target parameters.

- WL.Server.sendMessage(applicationId, notificationOptions)
  - o applicationId (mandatory) The name of the MobileFirst application
  - o notificationOptions (mandatory) A JSON block containing message properties

For a full list of message properties, refer to the WL.Server.sendMessage API in the API reference of user documentation

## Sample application

Before running the application, check the adapter's PushAdapter-impl.js file and verify that the WL.Server.sendMessage() method use the correct application name. The correct application name can be determined from the id attribute in application-descriptor.xml.
