Native iOS applications

Overview

This tutorial further elaborates on the available JSONStore APIs for Native iOS development.

Prerequisite: Make sure the MobileFirst Native SDK was added to the Xcode project. Follow the tutorial: Adding the MobileFirst Platform Foundation SDK to iOS applications (../../adding-the-mfpf-sdk/adding-the-mfpf-sdk-to-ios-applications/).

Jump to:

- Adding JSONStore
- Basic Usage
- Advanced Usage
- Sample application

Adding JSONStore

1. Edit the existing podfile, located at the root of the Xcode project. Add to the file:

pod 'IBMMobileFirstPlatformFoundationJSONStore'

2. From a **Command-line** window, navigate to the root of the Xcode project and run the command: pod install - note that this action may take a while.

Whenever you want to use JSONStore, make sure that you import the JSONStore header: Objective-C:

#import <IBMMobileFirstPlatformFoundation/IBMMobileFirstPlatformFoundationJSONStore.h>

Swift:

import IBMMobileFirstPlatformFoundationJSONStore

Basic Usage

Open

Use openCollections to open one or more JSONStore collections.

Starting or provisioning a collections means creating the persistent storage that contains the collection and documents, if it does not exists.

If the persistent storage is encrypted and a correct password is passed, the necessary security procedures to make the data accessible are run.

For optional features that you can enable at initialization time, see **Security, Multiple User Support** and **MobileFirst Adapter Integration** in the second part of this tutorial.

```
NSError *error = nil;

JSONStoreCollection* collection = [[JSONStoreCollection alloc] initWithName:@"people"];
[collection setSearchField:@"name" withType:JSONStore_String];
[collection setSearchField:@"age" withType:JSONStore_Integer];

[[JSONStore sharedInstance] openCollections:@[collection] withOptions:nil error:error];
```

Get

Use getCollectionWithName to create an accessor to the collection. You must call openCollections before you call getCollectionWithName.

```
NSString *collectionName = @"people";

JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];
```

The variable collection can now be used to perform operations on the people collection such as add, find, and replace.

Add

Use addData to store data as documents inside a collection.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];

NSDictionary *data = @{@"name" : @"yoel", @"age" : @23};
[[collection addData:@[data] andMarkDirty:YES withOptions:nil error:error] intValue];
```

Find

Use findWithQueryParts to locate a document inside a collection by using a query. Use findAllWithOptions to retrieve all the documents inside a collection. Use findWithIds to search by the document unique identifier.

```
NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];
//Build a query part.

JSONStoreQueryPart *query = [[JSONStoreQueryPart alloc] init];
[query searchField:@"name" like:@"yoel"];
JSONStoreQueryOptions *options = [[JSONStoreQueryOptions alloc] init];

// returns a maximum of 10 documents, default: returns every document
[options setLimit:@10];

// Count using the query part built above.
NSArray *results = [collection findWithQueryParts:@[query] andOptions:options error:error];
```

Replace

Use replaceDocuments to modify documents inside a collection. The field that you use to perform the replacement is id, the document unique identifier.

```
NSError *error = nil;

NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];

//Replacing name 'carlos' with name 'carlitos'.<br/>
NSDictionary *replacement = @{@"_id": @1, @"json" : @{@"name" : @"chevy", @"age" : @23}};

[collection replaceDocuments:@[replacement] andMarkDirty:YES error:error];
```

This examples assumes that the document $\{ \underline{id} : 1, json : \{ name : 'yoel', age : 23 \} \}$ is in the collection.

Remove

Use removeWithIds to delete a document from a collection. Documents are not erased from the collection until you call markDocumentClean. For more information, see the **MobileFirst Adapter Integration** section later in this tutorial.

```
NSError *error = nil;

NSString *collectionName = @"people";

JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];

[collection removeWithIds:@[@1] andMarkDirty:YES error:error];
```

Remove Collection

Use removeCollectionWithError to delete all the documents that are stored inside a collection. This operation is similar to dropping a table in database terms.

```
NSError *error = nil;

NSString *collectionName = @"people";

JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];

BOOL removeCollectionWorked = [collection removeCollectionWithError:error];
```

Destroy

Use destroyDataAndReturnError to remove the following data:

- All documents
- All collections
- All Stores See **Multiple User Support** later in this tutorial
- All JSONStore metadata and security artifacts See Security later in this tutorial

```
NSError *error = nil;
[[JSONStore sharedInstance] destroyDataAndReturnError:error];
```

Advanced Usage

Security

You can secure all the collections in a store by passing a <code>JSONStoreOpenOptions</code> object with a password to the <code>openCollections</code> function. If no password is passed, the documents of all the collections in the store are not encrypted.

Some security metadata is stored in the keychain (iOS).

The store is encrypted with a 256-bit Advanced Encryption Standard (AES) key. All keys are strengthened with Password-Based Key Derivation Function 2 (PBKDF2).

Use closeAllCollectionsAndReturnError to lock access to all the collections until you call openCollections again. If you think of openCollections as a login function you can think of closeAllCollectionsAndReturnError as the corresponding logout function.

Use changeCurrentPassword to change the password.

```
NSError *error = nil;

JSONStoreCollection *collection = [[JSONStoreCollection alloc] initWithName:@"people"];
[collection setSearchField:@"name" withType:JSONStore_String];
[collection setSearchField:@"age" withType:JSONStore_Integer];

JSONStoreOpenOptions *options = [JSONStoreOpenOptions new];
[options setPassword:@"123"];
[[JSONStore sharedInstance] openCollections:@[collection] withOptions:options error:error];
```

Multiple User Support

You can create multiple stores that contain different collections in a single MobileFirst application. The openCollections function can take an options object with a username. If no username is given, the default username is "jsonstore".

```
NSError *error = nil;

JSONStoreCollection *collection = [[JSONStoreCollection alloc] initWithName:@"people"];
[collection setSearchField:@"name" withType:JSONStore_String];
[collection setSearchField:@"age" withType:JSONStore_Integer];

JSONStoreOpenOptions *options = [JSONStoreOpenOptions new];
[options setUsername:@"yoel"];
[[JSONStore sharedInstance] openCollections:@[collection] withOptions:options error:error];
```

MobileFirst Adapter Integration

This section assumes that you are familiar with MobileFirst adapters. MobileFirst Adapter Integration is optional and provides ways to send data from a collection to an adapter and get data from an adapter into a collection.

You can achieve these goals by using functions such as WLClient invokeProcedure or your own instance of an NSURLConnection if you need more flexibility.

Adapter Implementation

Create a MobileFirst adapter and name it "**People**". Define it's procedures addPerson, getPeople, pushPeople, removePerson, and replacePerson.

```
function getPeople() {
  var data = { peopleList : [{name: 'chevy', age: 23}, {name: 'yoel', age: 23}] };
  WL.Logger.debug('Adapter: people, procedure: getPeople called.');
  WL.Logger.debug('Sending data: ' + JSON.stringify(data));
  return data;
function pushPeople(data) {
  WL.Logger.debug('Adapter: people, procedure: pushPeople called.');
  WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
  return;
}
function addPerson(data) {
  WL.Logger.debug('Adapter: people, procedure: addPerson called.');
  WL.Logger.debug('Got data from JSONStore to ADD: ' + data);
  return;
}
function removePerson(data) {
  WL.Logger.debug('Adapter: people, procedure: removePerson called.');
  WL.Logger.debug('Got data from JSONStore to REMOVE: ' + data);
  return;
function replacePerson(data) {
  WL.Logger.debug('Adapter: people, procedure: replacePerson called.');
  WL.Logger.debug('Got data from JSONStore to REPLACE: ' + data);
  return;
}
```

Load data from MobileFirst Adapter

To load data from a MobileFirst Adapter use WLClient invokeProcedure.

```
// Start - LoadFromAdapter
@interface LoadFromAdapter : NSObject<WLDelegate>
@end
@implementation LoadFromAdapter
-(void)onSuccess:(WLResponse *)response {
 NSArray *loadedDocuments = [[response getResponseJson] objectForKey:@"peopleList"];
 // handle success
}
-(void)onFailure:(WLFailResponse *)response {
 // handle success
}
@end
// End - LoadFromAdapter
NSError *error = nil;
WLProcedureInvocationData *invocationData = [[WLProcedureInvocationData alloc] initWithAdapterName:
@"People" procedureName:@"getPeople"];
LoadFromAdapter *loadDelegate = [[LoadFromAdapter alloc] init];
WLClient *client = [[WLClient sharedInstance] init];
[client invokeProcedure:invocationData withDelegate:loadDelegate];
```

Get Push Required (Dirty Documents)

Calling allDirtyAndReturnError returns and array of so called "dirty documents", which are documents that have local modifications that do not exist on the back-end system.

```
NSError* error = nil;
NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];
NSArray *dirtyDocs = [collection allDirtyAndReturnError:error];
```

To prevent JSONStore from marking the documents as "dirty", pass the option andMarkDirty:NO to add, replace, and remove.

Push changes

To push changes to a MobileFirst adapter, call the findAllDirtyDocuments to get a list of documents with modifications and then use WLClient invokeProcedure. After the data is sent and a successful response is received make sure you call markDocumentsClean.

```
// Start - PushToAdapter
@interface PushToAdapter :NSObject<WLDelegate>
@end
@implementation PushToAdapter
-(void)onSuccess:(WLResponse *)response {
 // handle success
}
-(void)onFailure:(WLFailResponse *)response {
 // handle faiure
}
@end
// End - PushToAdapter
NSError* error = nil;
NSString *collectionName = @"people";
JSONStoreCollection *collection = [[JSONStore sharedInstance] getCollectionWithName:collectionName];
NSArray *dirtyDocs = [collection allDirtyAndReturnError:error];
WLProcedureInvocationData *invocationData = [[WLProcedureInvocationData alloc] initWithAdapterName:
@"People" procedureName:@"pushPeople"];
[invocationData setParameters:@[dirtyDocs]];
PushToAdapter *pushDelegate = [[PushToAdapter alloc] init];
WLClient *client = [[WLClient sharedInstance] init];
[client invokeProcedure:invocationData withDelegate:pushDelegate];
```

Sample application
