General information when developing for iOS

fork and edit tutorial (https://github.com/MobileFirst-Platform-Developer-Center/DevCenter/#fork-destination-box) | report issue (https://github.com/MobileFirst-Platform-Developer-Center/DevCenter/issues/new)

Overview

In this tutorial a general development information for the iOS environment will be presented, covering topics such as project structure, accessing native capabilities using Apache Cordova, environment-specific & design resources and deployment.

Project structure

An iPhone/iPad application that is developed by using IBM MobileFirst Platform comprises the following components:

- An Objective-C ("native") Main App Delegate is provided, and hosts an instance of a UIWebView component
- www.bundle files, that are written in HTML, CSS and JavaScript, and that run in the UIWebView instance
- A set of Objective-C and JavaScript libraries that provide access to various iOS features and capabilities
- All application components, including the web code that the developer provides, are packaged into a single universal iOS application

If a source control management system is used (such as Rational Team Concert, Git, Subversion and so on...), see the user documentation topic: "Integrating with source control system".

Designing for iOS

Guidelines

Starting iOS7, the design language of the operating system has changed drastically.
It is therefore highly encouraged and useful for developers to consult the Apple iOS Human Interface Guidelines at https://developer.apple.com/library/ios/documentation/UserExperience/Conceptual/MobileHIG/ (https://developer.apple.com/library/ios/documentation/UserExperience/Conceptual/MobileHIG/).

When developing for iOS, it is also useful to consult the iOS Developer Library at https://developer.apple.com/library/ios/navigation/ (https://developer.apple.com/library/ios/navigation/).

Resolutions

iOS devices have various screen resolutions:

- iPhone 1/2/3/3GS – 320 x 480
- iPhone 4/4S – 640 x 960
- iPhone 5/5s – 640 x 1136
- iPhone 6 - 1334 x 750
- iPhone 6 plus - 1920 x 1080
- iPad 1/2/mini – 768 x 1024
- iPad 3/4/5 – 1,536 x 2,048

When displaying graphical elements on wider screens, iOS automatically scales images and fonts to the appropriate ratio.
For example, on a 640-pixel wide screen, a 100-pixel wide image is scaled by 640/320 (= 2) to 200 pixels in width, and the text that is displayed with an 18-pixel font is displayed with a 36-pixel font.

The following then falls under the responsibility of the developer:

- Ensure that images look good at all resolutions:
  - Provide images for the environment with the highest resolution requirements.
  - In the CSS, scale the image width to the lower resolution.
  - In the previous example, provide an image with a width of 200 pixels, and in the CSS, scale it to 100 pixels. iOS scales it back by a factor of 2 to be 200 pixels wide.
- Make sure that text is displayed appropriately at all resolutions
- Consider specifying font sizes in ems, rather than in pixels.

Environment-specific images

Image file sizes differ depending on your iDevice. For more information, see the Apple iOS UI Development Guidelines for icon and image sizes (https://developer.apple.com/library/ios/documentation/userexperience/conceptual/mobilehig/IconMatrix.html#//apple_ref/doc/uid/TP40006556-CH27-SW1).

Apache Cordova

The Apache Cordova framework can be used in iOS applications to access the native elements of a device, such as contacts, geo-location services, media services, or the accelerometer.

For more information about Apache Cordova development, see the *Apache Cordova overview tutorial*.

Deployment

iOS application deployment is done through the Apple App Store.

Important: Before you build a production version of your application, make sure that the `worklightSettings` property inside the application's application-descriptor.xml file is set to `false`.

Go through the App Store approval process.
Manage your apps on the App Store.
