Push Notifications Overview

Overview

IBM MobileFirst Platform Foundation provides a unified set of API methods to send notifications to devices on which MobileFirst applications are installed. Notification can be sent in 2 different ways: based on sources of events or based on tags.

Agenda

- What is push notification?
- Push notification types
- REST API for Push notifications
- Supported environments

What is push notification?

Push notifications is the ability of a mobile device to receive messages that are "pushed" from a server.

Notifications are received regardless of whether the application is currently running. Notifications can take several forms:

- **Alert (all)**: a pop-up text message
- **Badge (iOS), Tile (W8, WP8)**: a graphical representation that allows a short text or image
- **Banner (iOS), Toast (W8, WP8)**: a disappearing pop-up text message at the top of the device display
- **Sound (all)**: a sound file playing when a notification is received

- **Interactive (iOS 8)**: action buttons inside the **Banner** of a received notification

Device support

Push notifications are supported for the following mobile platforms:

- Android 2.3.5, 4.x, 5.x
- iOS 6, 7, and 8
- Windows Phone 8.x
- Windows 8

Push notification types

Event Source notifications

Event source push notifications are notification messages that are targeted to devices with a user subscription.
[collapse label="Expand to read more"]

Notification architecture

Terminology

Event source

A push notification channel to which mobile applications can register. An event source is defined within a MobileFirst adapter.

Device token

A unique identifier, obtained from the push mediator (Apple, Google, or Microsoft), which identifies the request of a specific mobile device to receive notifications from the MobileFirst Server.

User ID

A unique identifier for a user. Obtained through authentication or other unique identifier such as a persistent cookie.

Application ID

MobileFirst application ID. Identifies a specific MobileFirst application on the mobile market.

Subscription

To start receiving push notifications, an application must first subscribe to a push notification event source.
An event source is declared in the MobileFirst adapter that is used by the application for push notification services.

The end user must approve the push notification subscription.
After the subscription is approved, the device registers with an Apple, Google, or Microsoft push

server to obtain a token that is used to identify the device ("Allow notifications for application X on device Y"), and sends a subscription request to the MobileFirst Server. *This operation is performed automatically by the MobileFirst framework.*

Demonstration

(https://developer.ibm.com/mobilefirstplatform/wp-content/uploads/sites/32/2015/05/08_01_subscription_1.jpg)

When the subscribe API method is called, the device registers with a push service mediator and obtains a device token (done automatically by the framework).

(https://developer.ibm.com/mobilefirstplatform/wp-content/uploads/sites/32/2015/05/08_01_subscription_2.jpg)

When the token is obtained, the application subscribes to an event source. Both actions are done automatically by a single API method call, as described in Subscription management.

Sending notifications

IBM MobileFirst Platform Foundation provides a unified API for push notification.

Use the adapter API for the following actions:

- Managing subscriptions
- Pushing and polling notifications from a back end
- Sending push notifications to devices

Use the application API for the following actions:

- Subscribing to and unsubscribing from push-notification event sources
- Handling incoming notifications

Before a notification can be sent, it must first be retrieved from the back end.

An event source can either **poll** notifications from the back-end system, or wait for the back-end system to explicitly **push** a new notification.
When a notification is retrieved by the adapter, it is processed and sent through the corresponding push service mediator (Apple, Google, or Microsoft).

Some custom logic can be added in the adapter to preprocess notifications. The push service mediator receives the notification and sends it to a device.
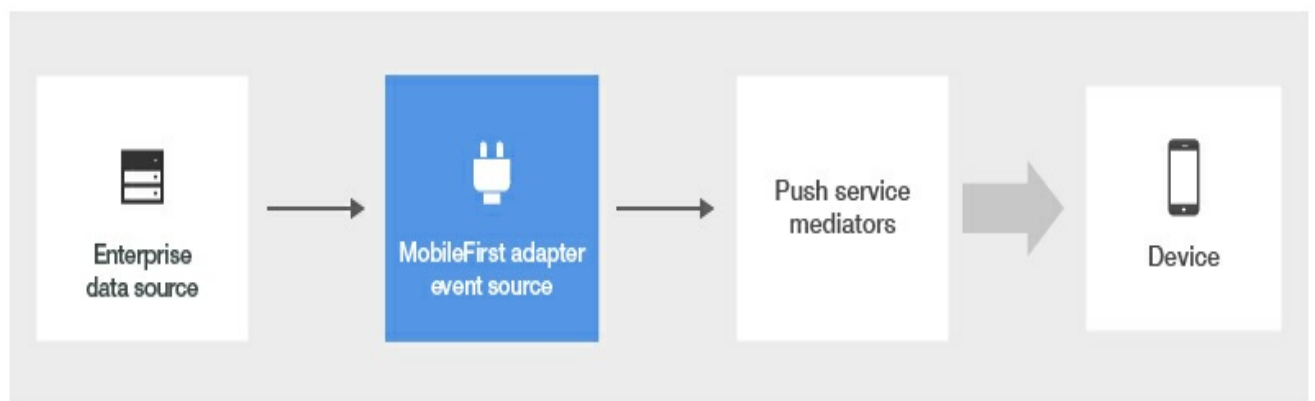

Demonstration
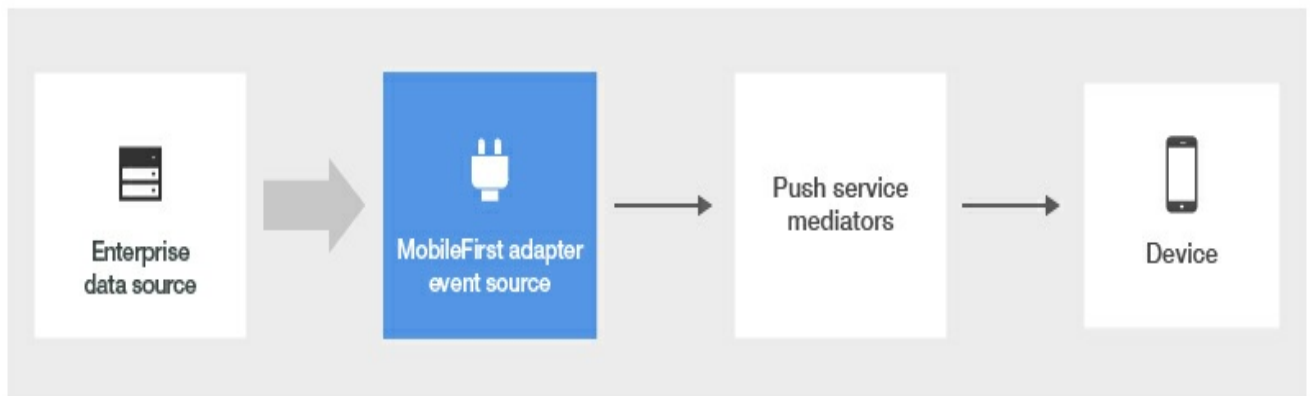

(https://developer.ibm.com/mobilefirstplatform/wp-content/uploads/sites/32/2015/05/08_01_sending_notification_1.jpg)

Notifications are retrieved by the MobileFirst adapter event source, either by poll or by push from the back-end system.
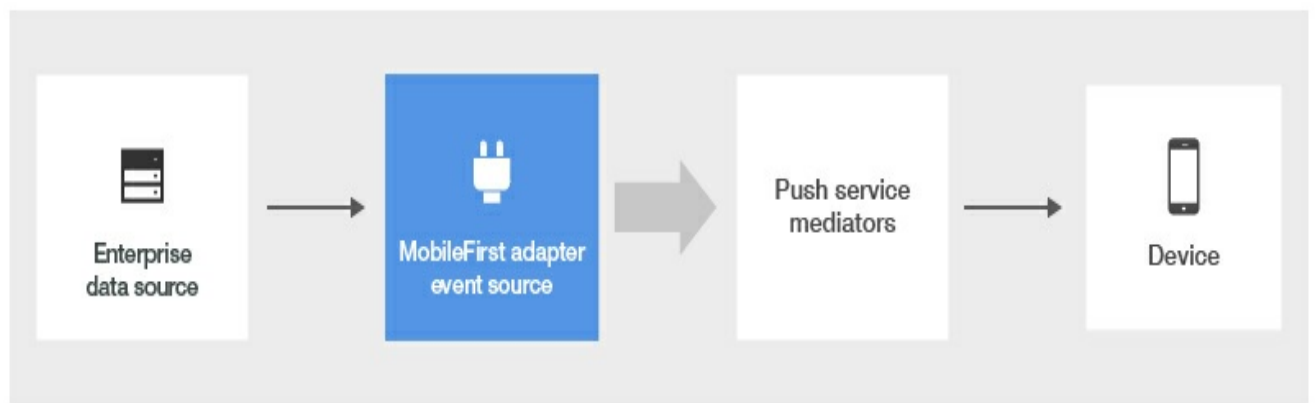

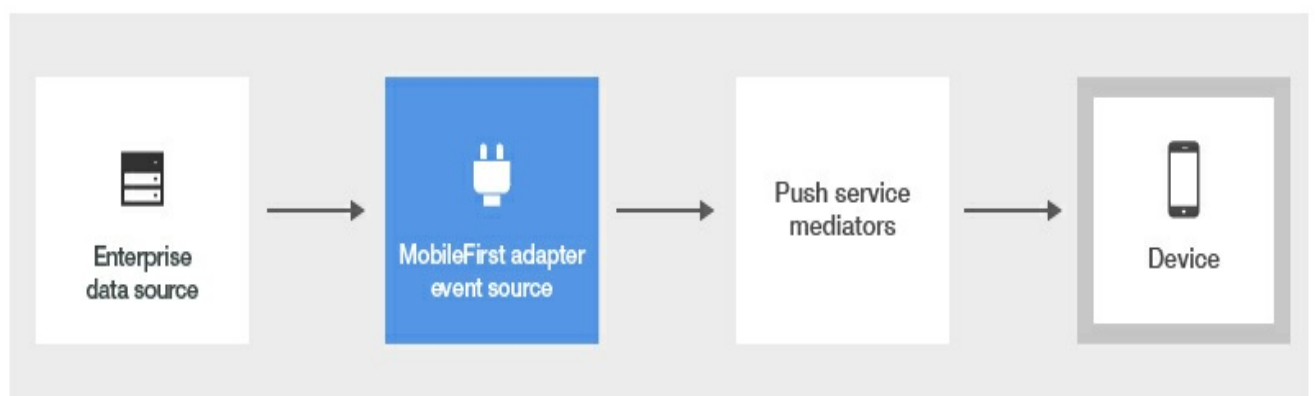

(https://developer.ibm.com/mobilefirstplatform/wp-
content/uploads/sites/32/2015/05/08_01_sending_notification_2.jpg)

The adapter processes the notification and sends it to a push service mediator.

(https://developer.ibm.com/mobilefirstplatform/wp-
content/uploads/sites/32/2015/05/08_01_sending_notification_3.jpg)

The push service mediator sends a push notification to the device.

(https://developer.ibm.com/mobilefirstplatform/wp-
content/uploads/sites/32/2015/05/08_01_sending_notification_4.jpg)

The device processes the received notification.

Subscription management

User subscription

Subscription

An entity that contains a user ID, a device ID, and an event source ID. It represents the intent of the user to receive notification from a specific event source.

Creation

The user subscription for an event source is created when the user first subscribes to the event source from any device.

Deletion

A user subscription is deleted when the user unsubscribes from the event source from all the user's devices.

Notification

While the user subscription exists, the MobileFirst Server can produce push notifications for the subscribed user. These notifications can be delivered by the adapter code to all or some of the devices that the user subscribed from.

Device subscription

A device subscription belongs to a user subscription and exists in the scope of a specific user and event source. A user subscription can have several device subscriptions.

The device subscription is created when the application on a device calls the subscribe method. The device subscription is deleted either by an application that calls the *unsubscribe* method or when the push mediator informs the MobileFirst Server that the device is permanently not accessible.

[/collapse]

Tag notifications

Tag push notifications are notification messages that are targeted to all the devices that are subscribed to a particular tag.

Broadcast notifications

Broadcast push notifications are a form of tag push notifications that are targeted to all subscribed devices.

Unicast notifications

Unicast notifications are targeted to a particular device or a `userID`. Unicast notifications do not require any additional setup and are enabled by default when the MobileFirst application is enabled for push notifications.

> For more information about unicast notifications, see the topic about sending push notifications, in the user documentation.

Interactive notifications

iOS 8 and above only
Interactive push notifications enables action buttons to be added for received notifications.

Silent notifications

iOS 7 and above only
Silent push notifications enables notifications to be sent without disturbing the user.

REST API for Push notifications

MobileFirst Platform Foundation exposes a REST API endpoint that can be accessed by non-mobile clients. It is another way to use the push service without needing to develop and deploy MobileFirst adapters.

> For more information about the REST API for push notification, see the topic about REST API Runtime Services, in the user documentation.
